

Attention mechanism enable neural network to select focus on specific part of input sequence.

## Transformer

→ 4 types of neural network  
to handle sequences to sequences  
of changing data.

ex → machine translation  
question answering  
text summary.

word embedding → word embedding is a natural language processing technique that converts word into numerical vectors, allowing computers to understand their meaning and relationships. These vectors are dense, it means they contain many non-zeros values, and it alone.

ex → TF-IDF, word2vec,

static word embedding → static word embedding provides a single, fixed vector for each word.

static embedding are simple and faster

contextual word embedding →

Contextual word embeddings generate a unique vector for a word based on the specific sentence it appears in.

Contextual embeddings are more accurate because they can capture different meanings of a word, such as the word "bank" in "river bank" versus "money bank".

Self attention mechanism

↳ self attention is a way to convert static embedding to dynamic contextual embedding.

Positional encoding provides transformers with information about the order of tokens in a sequence.

multi-head attention is an extension of the self attention mechanism, used in the transformer architecture, which allows the model to focus on different parts of the input sequence from multiple perspectives.

~~Layer Normalization~~ is a technique used to normalize the inputs across the features for each data point.

Layer normalization in transformer is a crucial technique that stabilizes and speeds up model training by normalizing the activations of each layer to have a mean of zero and a standard deviation of one.

Feed forward layers → This layer applied in both part of the transformer, encoder and decoder. This layer represent non-linearity and complex pattern of the network. captures

## Softmax layer

The softmax layer in transformer converts a vector of raw scores into a probability distribution.

There are two roles of softmax layer:

- ① In the attention mechanism
- ② Final output classification

=> Within the self-attention layer, it calculates a probability distribution over the input tokens.

=> In the final layer, it converts the model's final output into a probability for each possible class in a multi-class classification task.

masked multi-head attention is used in the decoder of a transformer to prevent the model from seeing the future when predicting the next token in a sequence.

1 to  $n_{\text{f}}$

what are diffusion models →

Diffusion models are a class of generative AI models that generate high resolution images of varying quality.

They work by gradually adding noise gaussian noise to the original data in the forward diffusion process and then learning to remove the noise in the reverse diffusion process.

They are latent variable model

① Forward diffusion process → The forward diffusion process is the forward diffusion steps in markov chain of diffusion steps in which we slowly and randomly add noise to the original data.

② Reverse diffusion process → the reverse diffusion process tries to reverse the diffusion process to generate original data from the noise.

$$q(x_t | x_{t+1}) = N(x_t; \underbrace{\mu_t}_{\text{mean}} + \underbrace{\beta_t \cdot x_{t+1}}_{\text{Variation}}, \sigma^2)$$

output  
 Image      mean  
 (noisy Image)

Normal distribution / gaussian distribution

$\mu_t = 0, \sigma^2 = 1$

$\beta_t$  → control the amount of noise add in each time step

$$p_\theta(x_{t+1} | x_t) = N(x_{t+1}; \underbrace{\mu_\theta(x_t, t)}_{\text{mean}}, \underbrace{\Sigma_\theta(x_t, t)}_{\text{Variation}})$$

lens      noise      output      mean      variance  
 Noisy      Image

stable diffusion works in a compressed latent space to be significantly faster and require less computational power, while maintaining high quality outputs.

## Tokenization

(Breaking into)

Tokenization is the process of breaking down text into smaller units called tokens.

These tokens can be words, subwords, or even characters, depending on the approach.

Tokenization is fundamental in natural language processing (NLP) and generating AI because it converts raw text into a form that model can process and understand.

Text → Generating AI is fascinating

tokens = ["Generating", "AI", "is", "fascinating"]

subword tokenization →

subword tokenization involves breaking word into smaller, meaningful subword unit.

Word → fascination

Subword tokens: ['fas', 'cina', 'tion']

## Cosine Similarity

Cosine similarity is a metric used to measure how similar two vectors are, regardless of their magnitude.

It is used in text analysis, recommendation systems and clustering task.

Cosine Similarity

$$\text{Cosine Similarity} = \frac{\mathbf{A} \cdot \mathbf{B}}{\|\mathbf{A}\| \|\mathbf{B}\|}$$

Example:  $\begin{bmatrix} 1 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 0 & 1 & 1 \end{bmatrix} = 1$

$\begin{bmatrix} 1 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 0 & 1 & 0 \end{bmatrix} = 0$

$\begin{bmatrix} 1 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & 0 \end{bmatrix} = 1$

$\begin{bmatrix} 1 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 0 & 1 & 0 \end{bmatrix} = 0$

$\begin{bmatrix} 1 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 1 & 0 \end{bmatrix} = 1$

$\begin{bmatrix} 1 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 1 & 1 \end{bmatrix} = \sqrt{3}$

$\begin{bmatrix} 1 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 1 & 1 \end{bmatrix} = \sqrt{3}$
